Lecture 4: Congestion Control I
(End System Algorithms)
Stefan Savage
Outline

- Projects

- Congestion management
  - Basics
  - Ramakrishnan & Jain (8)
  - Jacobson & Karels (88)
  - Some TCP details
Project mechanics

- Teams of 2-4
  - Please try to figure this out in the next week
  - Feel free to use the mailing list to find others with like interests
  - If you can’t find anyone, let me know
- You decide topic
  - Let’s try to finalize by October 11th
  - Come talk to me during office hours
  - I would like a .5-1 page project proposal
- Start working early so you don’t crash
- Final project report and presentation
  - 6-8 pages
  - 10 minute presentation
Example projects

- Implementation
  - A tool that monitors web surfing and graphs the various sources of latency (RTT, congestion signals, DNS lookup)
- Simulation
  - Compare different congestion control algorithms in ns
- Analysis
  - Using network trace (from CAIDA) examine behavior of multi-player network games
  - Fingerprinting of machines by analyzing TCP behavior
- Survey
  - Survey of network load balancing algorithms
  - Mechanisms for sending video over loss wireless channels
- White paper
  - Propose new architecture for providing secure name service
More on projects

- I will put a more extensive list of projects on Web page
  - My ideas, CAIDA’s projects, projects from last year, projects from other schools
  - You are encouraged to think of your own – these are just to give you ideas… do something that interests you

- Start thinking about this now…
Today’s question

- How fast should the sender transmit data?
  - Not too slow
  - Not too fast
  - Just right…

- Should not be faster than the receiver can process
  - Flow control (last week)

- Should not be faster than the network can process
  - Congestion control
Quick review:
How routers/switches work

1. Packet arrives at input interface and is queued
2. Lookup address in forwarding table and find output interface
3. Switch packet to output interface
4. Packet is queued for transmission
5. Packet sent
Quick review:
How Queuing works

- Queues absorb **short-term** traffic bursts
- Long term overload will cause packets to be dropped

- Two components to a queuing mechanism
  - **Scheduling**: which packets are sent from queue?
  - **Buffer management**: what happens when queue is full?

- Most of the Internet is FIFO/Drop Tail
  - **First-In-First-Out**: Packets leave in same order they arrive
  - **Drop tail**: When queue is full, newly arriving packets dropped
  - There are other policies and we’ll talk about some of them another time…
Impact of load on FIFO/Drop-Tail Queues

Network Load vs. Throughput and Latency

- Congestion packet loss
- Congestion collapse
Congestion collapse

- Rough definition: “When an increase in network load produces a decrease in useful work”

- Why does it happen?
  - Sender sends faster than bottleneck link speed
    » What's a bottleneck link?
  - Packets queue until dropped
  - In response to packets being dropped, sender retransmits
  - Repeat in steady state
  - Everyone does the same thing…
What can be done?

- **Increase network resources**
  - More buffers for queuing
  - Increase link speed
  - Pros/Cons of these approaches?

- **Reduce network load**
  - Send data more slowly
  - How much more slowly?
  - When to slow down?
Congestion management goals

- Efficiency
  - Utilize available bandwidth as much as possible

- Fairness
  - All hosts get equal access to bandwidth

- Distributed implementation
  - Only require state at endpoints

- Convergence
  - For constant load, arrive at single solution for using/sharing bandwidth
Proactive vs reactive approaches

- **Congestion avoidance**: try to stay to the left of the knee
- **Congestion control**: try to stay to the left of the cliff

![Diagram showing network load vs throughput and latency with knee and cliff concepts](image-url)
Key questions

- How to detect congestion?
- How to limit sending data rate?
- How fast to send?
- How to achieve stability?
How to detect congestion?

- Explicit congestion signaling
  - Source Quench: ICMP message from router to sender
  - DECBit / Explicit Congestion Notification (ECN):
    » Router marks packet based on queue occupancy
    » Receiver tells sender if queue is getting too full
  - Hop-by-hop backpressure

- Implicit congestion signaling
  - Packet loss
    » Assume congestion is primary source of packet loss
    » Lost packets (timeout, NAK) indicate congestion
  - Packet delay
    » Round-trip time increases as packets queue
    » Packet inter-arrival time is a function of bottleneck link
    » Pros/Cons?
How to limit the sending rate?

- **Window-based (TCP)**
  - Artificially constrain number of outstanding packets allowed in network
  - Increase window to send faster; decrease to send slower
  - Pro: Cheap to implement; good failure properties
  - Con: creates bursty traffic

- **Rate-based (Many streaming media protocols)**
  - Two parameters (period, packets)
  - Allow sending of $x$ packets in period $y$
  - Pro: smooth traffic
  - Con: per-connection timers; what if receiver fails
How fast to send?

- Ideally: Keep equilibrium at “knee” of power curve
  - Find “knee” somehow
  - Keep number of packets “in flight” the same
  - Don’t send a new packet into the network until you know one has left (i.e. by receiving an ACK)
  - What if you guess wrong, or if bandwidth availability changes?

- Compromise: adaptive approximation
  - If congestion signaled, reduce sending rate by x
  - If data delivered successfully, increase sending rate by y
  - How to relate x and y? Most choices don’t converge…
How to achieve stability?

- Additive Increase, Multiplicative Decrease (AIMD)
  - Increase sending rate by a constant (e.g. by 1500 bytes)
  - Decrease sending rate by a linear factor (e.g. divide by 2)

- Rough intuition for why this works (from JK88)
  - Let $L_i$ be queue length at time $i$
  - In steady state: $L_i = N$, where $N$ is a constant
  - During congestion: $L_i = N + y L_{i-1}$, where $y > 0$
  - If $y$ is large (close to 1), queue size increases exponentially
    » Must reduce sending rate exponentially as well (multiplicative decrease)
DECbit scheme: Ramakrishnan\&Jain88

- Congestion avoidance
  - Goal is to operate around the knee

- Explicit congestion signaling
  - If average queue size is over threshold routers mark packets
  - Receiver echoes mark in ACKs

- Window-based
  - Sender monitors frequency of marked ACKs
  - If more frequent, reduce window; else increase window

- AIMD-based algorithm
  - Increase by window by 1/8, decrease by 7/8
Complexities

- **Router issues**
  - How to set threshold for power optimization? Hysteresis?
  - How to measure queue length?
    - Instantaneous: oscillates too much
    - Fixed period: bias for different rtts
    - EWMA: also has rtt bias
    - Regeneration points: imperfect under heavy load

- **Host issues**
  - What signifies congestion? 50% marked bits
  - Which acks do you use? Recent acks don’t have causal relationship with decision
  - Simulation to justify decrease by 7/8 increase by 1/8
Impact

- Implemented as part of DECnet (once a big deal)
- Influenced Van Jacobson in his work
- Was inspiration for modern router-based congestion control mechanisms (RED+ECN)

- Why not successful?
  - Required universal router support
  - Wasn’t part of BSD Unix
Jacobson & Karels 88

- Seminal paper in computer networking
  - 5th most cited paper in all computer science

- Context: 1986 brings huge congestion collapse
  - LBL<->Berkeley link throughput decreases by 1000x
  - Motivation for paper: Why? and how to fix it?

- Key principle: packet conservation
  - Once equilibrium is reached, only send new packet once old packet has been received or dropped (constant load)
  - Why is TCP not obeying this principle? Hmmm….
Ways to violate packet conservation

- Connection never reaches equilibrium
  - Slow start (still a big problem)

- Premature sending of new packets
  - Adaptive timeouts

- Equilibrium can’t be reached because of resource limits along path
  - Congestion avoidance (misnamed)
Some TCP details

- Congestion control, not avoidance
- Implicit congestion detection
  - Packet losses
- Window-based
  - Makes sense make congestion control and flow control using same rate-limiting mechanism
  - $rwin$: advertised flow control window from receiver
  - $cwnd$: congestion control window
    - Estimate of network limit on # of outstanding packets
  - Sender can only send $\text{MIN}(rwin, cwnd)$ at any time
- AIMD-based algorithm
  - Increase window by $1/cwnd$, decrease by 2
Congestion avoidance

- If packet is ACKd then increase $cwnd$ by $\text{MSS}\times\text{MSS}/cwnd$ (fraction of $cwnd$)
  - Approximates $1/cwnd$ per window
- If timeout then divide $cwnd$ by 2

![Additive Increase/Multiplicative Decrease](chart)

- $cwnd$ vs. round-trip times
Adaptive timing

- How long to wait for a packet’s acknowledgement?
  - Too short: spurious timeouts and retransmissions
  - Too long: wasted time

- Old TCP
  - Maintain weighted average of RTT samples: $R$
  - Timeout set to $R \times B$, where $B = 2$
  - Under high load, $B$ doesn’t reflect variation and spurious retransmissions occur

- Jacobson’s contributions
  - Estimate variation, $B$ based on same samples
  - After loss, increase timeout exponentially (by 2)
Slow start

- Goal: find the equilibrium sending rate
- Quickly increase sending rate until congestion detected
- Algorithm:
  - On new connection, or after timeout, set $cwnd=1$
  - For each segment acknowledged, increment $cwnd$ by 1
  - If timeout then divide $cwnd$ by 2, and set $ssthresh = cwnd$
  - If $cwnd >= ssthresh$ then exit slow start
- Why called slow? Its exponential after all…
Slow start growth example
Fast retransmit & recovery

- **Fast retransmit**
  - Timeouts are slow (1 second is fastest timeout on most TCPs)
  - When packet is lost, receiver still ACKs last in-order packet
  - Use 3 duplicate ACKs to indicate a loss
    » Why 3? When wouldn’t this work?

- **Fast recovery**
  - If there are still ACKs coming in, then no need for slow start
  - Divide $cwnd$ by 2 after fast retransmit
  - Increment $cwnd$ by $1/cwnd$ for each additional duplicate ACK
Fast retransmit & recovery

- Fast retransmit
- Fast recovery (increase cwnd by 1)

Diagram:
- Sender
  - 1
  - Ack 1
  - 2
  - 3
  - Ack 2
  - Ack 3
  - 4
  - Ack 3
  - 5
  - Ack 3
  - 6
  - Ack 3
  - 7
  - Ack 3
  - 4

- Receiver

3 Dup Ack

Fast retransmit
Putting it together

Slow Start + Congestion Avoidance

- Slow start
- Congestion avoidance
- ssthresh
- Timeout
Fast retransmit in action

Slow Start + Congestion Avoidance + Fast Retransmit

cwnd

round-trip times
Fast recovery in action

Slow Start + Congestion Avoidance + Fast Retransmit + Fast Recovery

cwnc
round-trip times
Delayed ACKs

- In request/response programs, want to combine an ACK to a request with a response in same packet
  - Wait 200ms before ACKing
  - Must ACK every other packet (or packet burst)
  - Impact on slow start?
- Must not delay duplicate ACKs
  - Why? What is the interaction with the congestion control algorithms?
Partial ACKs

- A partial ACK acknowledges only some of the packets outstanding at the start of Fast Recovery
  - Suggests that a second packet may have been lost
- Should you exit Fast Recovery and go into congestion avoidance, or continue in FR?
  - Hoe: Stay in Fast Recovery, retransmit packet after ACK
  - When all packets in window when FR was initiated have been ACKed, go into congestion avoidance
A TCP Taxonomy

- TCP Tahoe (1988)
  - Slow-Start, Fast Retransmit, Congestion Avoidance
- TCP Reno (1990)
  - Tahoe + Fast Recovery
- TCP New-Reno (1996)
  - Reno + Hoe’s partial ACK change that keeps TCP in Fast Recovery
- SACK TCP (1996)
  - Selective acknowledgements
- TCP Vegas (1993)
  - Contraversial attempts at real congestion avoidance
Discussion: Short Connections

- How do short connections and Slow-Start interact?
  - What happens when there is a drop in Slow-Start?
  - What happens when the SYN is dropped?
- Bottom line: Which packet gets dropped matters a lot
  - Syn
  - Slow-Start
  - Congestion avoidance
- Do you think most flows are short or long?
  - What’s the current most popular application?
  - What were the most popular applications when Slow-Start was developed?
Stuff to think about

- TCP is designed around the premise of cooperation
  - What happens to TCP if it competes with a UDP flow?
  - What if divide cwnd by 3 instead of 2 after a loss?
  - What happens if receiver lies about receiving packets?

- There are a number of assumptions
  - Losses mean congestion, re-ordering is rare, etc…

- There are a bunch of magic numbers
  - Decrease by 2x, increase by 1/cwnd, 3 duplicate acks, g=1/8, initial timeout = 3 seconds, etc
What's hot now?

- Equation-based congestion control
- Based on TCP behavior (TCP-friendliness)

\[ BW \approx \frac{MSS}{RTT} \frac{0.7}{\sqrt{p}} \]

- Goal: tailored congestion control response that is still “fair” wrt current implementations
  - E.g. multimedia wants smoother response after loss, but can afford slower ramp up
Summary

- Congestion avoidance
  - Slow down before congestion occurs
- Congestion control
  - Slow down when congestion occurs

- Can be implemented entirely end-to-end without network support using AIMD algorithms
- Benefit of router involvement?
For Next Time...
