This lecture

- Conditional Independence
- Bayesian (Belief) Networks: Syntax and semantics

Reading

- Chapter 14.1-14.2
Propositions and Random Variables

• Letting $A$ refer to a proposition which may either be true or false, $P(A)$ denotes the probability that $A$ is true – also denoted $P(A=\text{TRUE})$.

• $A$ is a called a binary or propositional random variable.

• We also have multi-valued random variables
  • e.g., *Weather* is one of \(<\text{sunny},\text{rain},\text{cloudy},\text{snow}>\)
Priors, Distribution, Joint

**Prior** or **unconditional probabilities** of propositions

e.g., \( P(\text{Cavity}) = P(\text{Cavity}=\text{TRUE}) = 0.1 \)
\( P(\text{Weather}=\text{sunny}) = 0.72 \)

correspond to belief prior to arrival of any (new) evidence

**Probability distribution** gives probabilities of all possible values
of the random variable.

weather is one of \(<\text{sunny}, \text{rain}, \text{cloudy}, \text{snow}>\)

\( P(\text{Weather}) = <0.72, 0.1, 0.08, 0.1> \)

(normalized, i.e., sums to 1)
Joint probability distribution

Joint probability distribution for a set of variables gives values for each possible assignment to all the variables.

\[ P(\text{Toothache}, \text{Cavity}) \] is a 2 by 2 matrix.

<table>
<thead>
<tr>
<th></th>
<th>Toothache=true</th>
<th>Toothache = false</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cavity=true</td>
<td>0.04</td>
<td>0.06</td>
</tr>
<tr>
<td>Cavity=false</td>
<td>0.01</td>
<td>0.89</td>
</tr>
</tbody>
</table>

**NOTE:** Elements in table sum to 1 \(\rightarrow\) 3 independent numbers.

\[ P(\text{Weather}, \text{Cavity}) \] is a 4 by 2 matrix of values:

<table>
<thead>
<tr>
<th>Weather=</th>
<th>sunny</th>
<th>rain</th>
<th>cloudy</th>
<th>snow</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cavity=True</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Cavity=False</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Conditional Probabilities

- **Conditional** or posterior probabilities
  
  e.g., \( P(\text{Cavity} \mid \text{Toothache}) = 0.8 \)

  What is the probability of having a cavity given that the patient has a toothache?

- **Definition of conditional probability:**
  
  \[ P(A \mid B) = \frac{P(A, B)}{P(B)} \text{ if } P(B) \neq 0 \]

- **Product rule** gives an alternative formulation:
  
  \[ P(A, B) = P(A \mid B)P(B) = P(B \mid A)P(A) \]
Bayes Rule

From product rule \( P(A, B) = P(A|B)P(B) = P(B|A)P(A) \), we can obtain Bayes' rule

\[
P(A | B) = \frac{P(B | A)P(A)}{P(B)}
\]
Bayes Rule: Example

Let $M$ be meningitis, $S$ be stiff neck

$P(M) = 0.0001$

$P(S) = 0.1$

$P(S|M) = 0.8$

$$P(M | S) = \frac{P(S | M)P(M)}{P(S)} = \frac{0.8 \times 0.0001}{0.1} = 0.0008$$

Note: posterior probability of meningitis still very small!
A generalized Bayes Rule

• More general version conditionalized on some background evidence E

\[ P(A \mid B, E) = \frac{P(B \mid A, E)P(A \mid E)}{P(B \mid E)} \]
Using the full joint distribution

<table>
<thead>
<tr>
<th></th>
<th>Toothache=true</th>
<th>Toothache = false</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cavity=true</td>
<td>0.04</td>
<td>0.06</td>
</tr>
<tr>
<td>Cavity=false</td>
<td>0.01</td>
<td>0.89</td>
</tr>
</tbody>
</table>

What is the unconditional probability of having a Cavity?

\[
P(\text{Cavity}) = P(\text{Cavity} \land \text{Toothache}) + P(\text{Cavity} \land \neg \text{Toothache})
\]
\[
= 0.04 + 0.06 = 0.1
\]

What is the probability of having either a cavity or a Toothache?

\[
P(\text{Cavity} \lor \text{Toothache})
\]
\[
= P(\text{Cavity,Toothache}) + P(\text{Cavity,} \neg \text{Toothache}) + P(\neg \text{Cavity,Toothache})
\]
\[
= 0.04 + 0.06 + 0.01 = 0.11
\]
Using the full joint distribution

<table>
<thead>
<tr>
<th></th>
<th>Toothache=true</th>
<th>Toothache = false</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cavity=true</td>
<td>0.04</td>
<td>0.06</td>
</tr>
<tr>
<td>Cavity=false</td>
<td>0.01</td>
<td>0.89</td>
</tr>
</tbody>
</table>

What is the probability of having a cavity given that you already have a toothache?

\[
P(Cavity | Toothache) = \frac{P(Cavity \land Toothache)}{P(Toothache)} = \frac{0.04}{0.04 + 0.01} = 0.8
\]
Normalization

Suppose we wish to compute a posterior distribution over random variable $A$ given $B=b$, and suppose $A$ has possible values $a_1,...,a_m$

We can apply Bayes' rule for each value of $A$:

$$P(A=a_i | B=b) = \frac{P(B=b | A=a_i)P(A=a_i)}{P(B=b)}$$

...\n
$$P(A=a_m | B=b) = \frac{P(B=b | A=a_m)P(A=a_m)}{P(B=b)}$$

Adding these up, and noting that $\sum_i P(A=a_i | B=b) = 1$:

$$P(B=b) = \sum_i P(B=b | A=a_i)P(A=a_i)$$

This is the normalization factor denoted $\alpha = 1/P(B=b)$:

$$P(A | B=b) = \alpha P(B=b | A)P(A)$$

Typically compute an unnormalized distribution, normalize at end

e.g., suppose $P(B=b | A)P(A) = \langle 0.4,0.2,0.2 \rangle$

then $P(A|B=b) = \alpha \langle 0.4,0.2,0.2 \rangle$

$$= \frac{\langle 0.4,0.2,0.2 \rangle}{(0.4+0.2+0.2)} = \langle 0.5,0.25,0.25 \rangle$$
Marginalization

Given a condition distribution \( P(X \mid Z) \), we can create the unconditional distribution \( P(X) \) by marginalization:

\[
P(X) = \sum_z P(X \mid Z=z) \, P(Z=z) = \sum_z P(X, Z=z)
\]

In general, given a joint distribution over a set of variables, the distribution over any subset (called a marginal distribution for historical reasons) can be calculated by summing out the other variables.
Conditioning

Introducing a variable as an extra condition:

\[ P(X|Y) = \sum_z P(X | Y, Z=z) P(Z=z | Y) \]

Intuition: often easier to assess each specific circumstance, e.g.,

\[
P(\text{RunOver} | \text{Cross}) = P(\text{RunOver} | \text{Cross}, \text{Light}=\text{green})P(\text{Light}=\text{green} | \text{Cross}) + P(\text{RunOver} | \text{Cross}, \text{Light}=\text{yellow})P(\text{Light}=\text{yellow} | \text{Cross}) + P(\text{RunOver} | \text{Cross}, \text{Light}=\text{red})P(\text{Light}=\text{red} | \text{Cross})
\]
Absolute Independence

- Two random variables $A$ and $B$ are (absolutely) **independent** iff
  \[ P(A, B) = P(A)P(B) \]

- Using product rule for $A$ & $B$ independent, we can show:
  \[
P(A, B) = P(A \mid B)P(B) = P(A)P(B)
  \]
  Therefore $P(A \mid B) = P(A)$

- If $n$ Boolean variables are independent, the full joint is:
  \[
P(X_1, \ldots, X_n) = \prod_i P(X_i)
  \]
  Full joint is generally specified by $2^n - 1$ numbers, but when independent only $n$ numbers are needed.

- Absolute independence is a very strong requirement, seldom met!!
Conditional Independence

• Some evidence may be irrelevant, allowing simplification, e.g.,

\[ P(\text{Cavity} \mid \text{Toothache, CubsWin}) = P(\text{Cavity} \mid \text{Toothache}) = 0.8 \]

• This property is known as **Conditional Independence** and can be expressed as:

\[ P(X \mid Y, Z) = P(X \mid Z) \]

which says that \( X \) and \( Y \) independent given \( Z \).

• If I have a cavity, the probability that the probe catches in it doesn't depend on whether I have a toothache:

1. \( P(\text{Catch} \mid \text{Toothache, Cavity}) = P(\text{Catch} \mid \text{Cavity}) \)
   
i.e., \text{Catch} is conditionally independent of \text{Toothache} given \text{Cavity}

The same independence holds if I haven't got a cavity:

2. \( P(\text{Catch} \mid \text{Toothache, ~Cavity}) = P(\text{Catch} \mid ~\text{Cavity}) \)
Conditional independence contd.

Equivalent statements to
\[ P(\text{Catch} \mid \text{Toothache, Cavity}) = P(\text{Catch} \mid \text{Cavity}) \quad (\ast) \]

1.a \[ P(\text{Toothache} \mid \text{Catch, Cavity}) = P(\text{Toothache} \mid \text{Cavity}) \]

\[ P(\text{Toothache} \mid \text{Catch, Cavity}) \\
\quad = P(\text{Catch} \mid \text{Toothache, Cavity}) P(\text{Toothache} \mid \text{Cavity}) / P(\text{Catch} \mid \text{Cavity}) \\
\quad = P(\text{Catch} \mid \text{Cavity}) P(\text{Toothache} \mid \text{Cavity}) / P(\text{Catch} \mid \text{Cavity}) \quad (\text{from } \ast) \\
\quad = P(\text{Toothache} \mid \text{Cavity}) \]

1.b \[ P(\text{Toothache, Catch} \mid \text{Cavity}) = P(\text{Toothache} \mid \text{Cavity}) P(\text{Catch} \mid \text{Cavity}) \]

\[ P(\text{Toothache, Catch} \mid \text{Cavity}) \\
\quad = P(\text{Toothache} \mid \text{Catch, Cavity}) P(\text{Catch} \mid \text{Cavity}) \quad \text{(product rule)} \\
\quad = P(\text{Toothache} \mid \text{Cavity}) P(\text{Catch} \mid \text{Cavity}) \quad (\text{from 1a}) \]
Using Conditional Independence

Full joint distribution can now be written as

\[
P(\text{Toothache}, \text{Catch}, \text{Cavity})
\]

\[
= (\text{Toothache}, \text{Catch} \mid \text{Cavity}) P(\text{Cavity})
\]

\[
= P(\text{Toothache} \mid \text{Cavity})P(\text{Catch} \mid \text{Cavity})P(\text{Cavity}) \quad \text{(from 1.b)}
\]

Specified by: \(2 + 2 + 1 = 5\) independent numbers

Compared to 7 for general joint

or 3 for unconditionally independent.
Belief (Bayes) networks

A simple, graphical notation for conditional independence assertions and hence for compact specification of full joint distributions.

Syntax:
1. a set of nodes, one per random variable
2. links mean parent “directly influences” child
3. a directed, acyclic graph
4. a conditional distribution (a table) for each node given its parents: \( P(X_i \mid \text{Parents}(X_i)) \)

In the simplest case, conditional distribution represented as a conditional probability table (CPT)
A two node net & Conditional probability table

- Node A is independent of Node B, so it is described by an unconditional probability $P(A)$.
- $P(\neg A)$ is given by $1 - P(A)$.

- Node B is conditionally dependent on A. It is described by four numbers, $P(B | A)$, $P(B | \neg A)$, $P(\neg B | A)$ and $P(\neg B | \neg A)$.
- This can be expressed as a 2 by 2 conditional probability table (CPT).
- But $P(\neg B | A) = 1 - P(B | A)$ and $P(\neg B | \neg A) = 1 - P(B | \neg A)$.
- Therefore, only two independent numbers in CPT.
Example

I'm at work, neighbor John calls to say my alarm is ringing, but neighbor Mary doesn't call. Sometimes it's set off by minor earthquakes. Is there a burglar?

Variables: Burglar, Earthquake, Alarm, JohnCalls, MaryCalls
