Formalization of DFA using lattices
Recall worklist algorithm

let m: map from edge to computed value at edge
let worklist: work list of nodes

for each edge e in CFG do
    m(e) := ∅ ▼

for each node n do
    worklist.add(n)

while (worklist.empty.not) do
    let n := worklist.remove_any;
    let info_in := m(n.incoming_edges);
    let info_out := F(n, info_in);
    for i := 0 .. info_out.length do
        let new_info := m(n.outgoing_edges[i]) U ▼
        info_out[i];
        if (m(n.outgoing_edges[i]) ≠ new_info))
            m(n.outgoing_edges[i]) := new_info;
            worklist.add(n.outgoing_edges[i].dst);
Using lattices

- We formalize our domain with a powerset lattice
- What should be top and what should be bottom?
Using lattices

- We formalize our domain with a powerset lattice
- What should be top and what should be bottom?
- Does it matter?
  - It matters because, as we’ve seen, there is a notion of approximation, and this notion shows up in the lattice
Using lattices

• Unfortunately:
  – dataflow analysis community has picked one direction
  – abstract interpretation community has picked the other

• We will work with the abstract interpretation direction

• Bottom is the most precise (optimistic) answer, Top the most imprecise (conservative)
Direction of lattice

- Always safe to go up in the lattice
- Can always set the result to $\top$
- Hard to go down in the lattice
- So ... Bottom will be the empty set in reaching defs
Worklist algorithm using lattices

let m: map from edge to computed value at edge
let worklist: work list of nodes

for each edge e in CFG do
  m(e) := ⊥

for each node n do
  worklist.add(n)

while (worklist.empty.not) do
  let n := worklist.remove_any;
  let info_in := m(n.incoming_edges);
  let info_out := F(n, info_in);
  for i := 0 .. info_out.length do
    let new_info := m(n.outgoing_edges[i]) ⊔
       info_out[i];
    if (m(n.outgoing_edges[i]) ≠ new_info))
      m(n.outgoing_edges[i]) := new_info;
      worklist.add(n.outgoing_edges[i].dst);
Termination of this algorithm?

• For reaching definitions, it terminates...

• Why?
  – lattice is finite

• Can we loosen this requirement?
  – Yes, we only require the lattice to have a finite height

• Height of a lattice: length of the longest ascending or descending chain

• Height of lattice \((2^S, \subseteq) = \)
Termination of this algorithm?

• For reaching definitions, it terminates...

• Why?
  – lattice is finite

• Can we loosen this requirement?
  – Yes, we only require the lattice to have a finite height

• Height of a lattice: length of the longest ascending or descending chain

• Height of lattice \((2^S, \subseteq) = | S |\)
Termination

Still, it’s annoying to have to perform a join in the worklist algorithm

```plaintext
while (worklist.empty.not) do
  let n := worklist.remove_any;
  let info_in := m(n.incoming_edges);
  let info_out := F(n, info_in);
  for i := 0 .. info_out.length do
    let new_info := m(n.outgoing_edges[i]) ⊔ info_out[i];
    if (m(n.outgoing_edges[i]) ≠ new_info)
      m(n.outgoing_edges[i]) := new_info;
      worklist.add(n.outgoing_edges[i].dst);
```

It would be nice to get rid of it, if there is a property of the flow functions that would allow us to do so
Even more formal

- To reason more formally about termination and precision, we re-express our worklist algorithm mathematically.

- We will use fixed points to formalize our algorithm.
Fixed points

- Recall, we are computing $m$, a map from edges to dataflow information.
- Define a global flow function $F$ as follows: $F$ takes a map $m$ as a parameter and returns a new map $m'$, in which individual local flow functions have been applied.
Fixed points

• We want to find a fixed point of $F$, that is to say a map $m$ such that $m = F(m)$

• Approach to doing this?

• Define $\downarrow$, which is $\bot$ lifted to be a map:
  $\downarrow = \lambda e. \bot$

• Compute $F(\downarrow)$, then $F(F(\downarrow))$, then $F(F(F(\downarrow)))$, ... until the result doesn’t change anymore
Fixed points

• Formally:

\[ \text{Soln} = \bigcup_{i=0}^{\infty} F^i(\perp) \]

• We would like the sequence \( F^i(\perp) \) for \( i = 0, 1, 2 \) ... to be increasing, so we can get rid of the outer join

• Require that \( F \) be monotonic:

\[ \forall a, b . a \sqsubseteq b \Rightarrow F(a) \sqsubseteq F(b) \]
Fixed points

\[ FF(\tilde{1}) \cong \tilde{1} \subseteq F(\tilde{1}) \]

\[ F(\tilde{1}) \subseteq FF(\tilde{1}) \]

\[ FF(\tilde{1}) \subseteq FFF(\tilde{1}) \]
Fixed points

\[
\begin{align*}
\tilde{I} \in F(\tilde{I}) \\
F(\tilde{I}) \subseteq F(F(\tilde{I})) \\
F^k(\tilde{I}) \subseteq F^{k+1}(\tilde{I}) \\
F^{k+1}(\tilde{I}) \subseteq F^{k+2}(\tilde{I})
\end{align*}
\]
So if $F$ is monotonic, we have what we want: finite height $\Rightarrow$ termination, without the outer join.

Also, if the local flow functions are monotonic, then global flow function $F$ is monotonic.
Another benefit of monotonicity

• Suppose Marsians came to earth, and miraculously give you a fixed point of F, call it fp.

• Then:

\[
\begin{align*}
I & \subseteq fp \\
F(I) & \subseteq fp \\
F(F(I)) & \subseteq fp \\
\vdots \\
0fp & \subseteq fp
\end{align*}
\]
Another benefit of monotonicity

• Suppose Marsians came to earth, and miraculously give you a fixed point of F, call it fp.

• Then:

\[
\begin{align*}
\tilde{I} \subseteq & \text{fp} \\
F(\tilde{I}) \subseteq & F(\text{fp}) \\
F(\tilde{I}) \subseteq & \text{fp} \\
F^2(\tilde{I}) \subseteq & \text{fp} \\
\vdots \\
o\text{fp} \subseteq & \text{fp}
\end{align*}
\]
Another benefit of monotonicity

- We are computing the least fixed point...
Recap

• Let’s do a recap of what we’ve seen so far

• Started with worklist algorithm for reaching definitions
Worklist algorithm for reaching defns

let m: map from edge to computed value at edge
let worklist: work list of nodes

for each edge e in CFG do
    m(e) := ∅

for each node n do
    worklist.add(n)

while (worklist.empty.not) do
    let n := worklist.remove_any;
    let info_in := m(n.incoming_edges);
    let info_out := F(n, info_in);
    for i := 0 .. info_out.length do
        let new_info := m(n.outgoing_edges[i]) U info_out[i];
        if (m(n.outgoing_edges[i]) ≠ new_info))
            m(n.outgoing_edges[i]) := new_info;
            worklist.add(n.outgoing_edges[i].dst);
Generalized algorithm using lattices

let m: map from edge to computed value at edge
let worklist: work list of nodes

for each edge e in CFG do
    m(e) := ⊥

for each node n do
    worklist.add(n)

while (worklist.empty.not) do
    let n := worklist.remove_any;
    let info_in := m(n.incoming_edges);
    let info_out := F(n, info_in);
    for i := 0 .. info_out.length do
        let new_info := m(n.outgoing_edges[i]) △ info_out[i];
        if (m(n.outgoing_edges[i]) ≠ new_info)
            m(n.outgoing_edges[i]) := new_info;
            worklist.add(n.outgoing_edges[i].dst);
Next step: removed outer join

- Wanted to remove the outer join, while still providing termination guarantee

- To do this, we re-expressed our algorithm more formally

- We first defined a “global” flow function F, and then expressed our algorithm as a fixed point computation
Guarantees

• If F is monotonic, don’t need outer join
• If F is monotonic and height of lattice is finite: iterative algorithm terminates
• If F is monotonic, the fixed point we find is the least fixed point.
What about if we start at top?

• What if we start with $\tilde{T}: F(\tilde{T}), F(F(\tilde{T})), F(F(F(\tilde{T})))$
What about if we start at top?

• What if we start with \( \top : F(\top), F(F(\top)), F(F(F(\top))) \)

• We get the greatest fixed point

• Why do we prefer the least fixed point?
