Virtual Memory

• The abstraction that the OS provides for managing memory is virtual memory (VM)
  ♦ Virtual memory enables a program to execute with less than its complete data in physical memory
    » A program can run on a machine with less memory than it “needs”
    » Can also run on a machine with “too much” physical memory
  ♦ Many programs do not need all of their code and data at once (or ever) – no need to allocate memory for it
  ♦ OS will adjust amount of memory allocated to a process based upon its behavior
  ♦ VM requires hardware support and OS management algorithms to pull it off
• Let’s go back to the beginning…
In the beginning...

- Rewind to the days of “second-generation” computers
  - Programs use physical addresses directly
  - OS loads job, runs it, unloads it

- Multiprogramming changes all of this
  - Want multiple processes in memory at once
    - Overlap I/O and CPU of multiple jobs
  - Can do it a number of ways
    - Fixed and variable partitioning, paging, segmentation
  - Requirements
    - Need protection – restrict which addresses jobs can use
    - Fast translation – lookups need to be fast
    - Fast change – updating memory hardware on context switch
Virtual Addresses

- To make it easier to manage the memory of processes running in the system, we’re going to make them use virtual addresses (logical addresses)
  - Virtual addresses are independent of the actual physical location of the data referenced
  - OS determines location of data in physical memory
  - Instructions executed by the CPU issue virtual addresses
  - Virtual addresses are translated by hardware into physical addresses (with help from OS)

- The set of virtual addresses that can be used by a process comprises its virtual address space (VAS)
  - VAS often larger than physical memory (64-bit addresses)
  - But can also be smaller (32-bit VAS with 8 GB of memory)
Virtual Addresses

• Many ways to do this translation…
  ♦ Start with old, simple ways, progress to current techniques
Fixed Partitions

• Physical memory is broken up into fixed partitions
  ♦ Hardware requirements: base register
  ♦ Physical address = virtual address + base register
  ♦ Base register loaded by OS when it switches to a process
  ♦ Size of each partition is the same and fixed
  ♦ How do we provide protection?

• Advantages
  ♦ Easy to implement, fast context switch

• Problems
  ♦ Internal fragmentation: memory in a partition not used by a process is not available to other processes
  ♦ Partition size: one size does not fit all (very large processes)

Variable Partitions

• Natural extension – physical memory is broken up into variable sized partitions
  ♦ Hardware requirements: base register and limit register
  ♦ Physical address = virtual address + base register
  ♦ Why do we need the limit register? Protection
    » If (physical address > base + limit) then exception fault

• Advantages
  ♦ No internal fragmentation: allocate just enough for process

• Problems
  ♦ External fragmentation: process creation and termination produces empty holes scattered throughout memory

Paging

- Paging solves the external fragmentation problem by using fixed sized units in both physical and virtual memory.
Programmer/Process View

• Programmers (and processes) view memory as one contiguous address space from 0 through N
  ♦ Virtual address space (VAS)
• In reality, pages are scattered throughout physical memory
  ♦ The mapping is invisible to the process
• Protection is provided because a process cannot reference memory outside of its VAS
  ♦ The address “0x1000” maps to different physical addresses in different processes
Paging

- Translating addresses
  - Virtual address has two parts: virtual page number and offset
  - Virtual page number (VPN) is an index into a page table
  - Page table determines page frame number (PFN)
  - Physical address is PFN::offset (“::” means concatenate)

- Page tables
  - Map virtual page number (VPN) to page frame number (PFN)
    - VPN is the index into the table that determines PFN
    - Will also refer to PFN as “physical page number”
  - One page table entry (PTE) per page in virtual address space
    - Or, one PTE per VPN
Page Lookups

Physical Address

Physical Memory

(Also used by Nachos)
Paging Example

- Pages are 4K
  - VPN is 20 bits ($2^{20}$ VPNs), offset is 12 bits
- Virtual address is 0x7468
  - Virtual page is 0x7, offset is 0x468 (first 12 bits of address)
- Page table entry 0x7 contains 0x2
  - Page frame number is 0x2
  - Seventh virtual page is at address 0x2000 (2nd physical page)
- Physical address = 0x2000 + 0x468 = 0x2468
Page Tables

- Page tables completely define the mapping between virtual pages and physical pages for an address space.
- Each process has an address space, so each process has a page table.
- Page tables are data structures maintained in the OS.
Page Table Entries (PTEs)

- Page table entries control mapping
  - The Modify bit says whether or not the page has been written
    » It is set when a write to the page occurs
  - The Reference bit says whether the page has been accessed
    » It is set when a read or write to the page occurs
  - The Valid bit says whether or not the PTE can be used
    » It is checked each time the virtual address is used
  - The Protection bits say what operations are allowed on page
    » Read, write, execute
  - The page frame number (PFN) determines physical page
Paging Advantages

• Easy to allocate memory
  ♦ Memory comes from a free list of fixed-sized chunks
  ♦ Allocating a page is just removing it from the list
  ♦ External fragmentation not a problem

• Easy to swap out chunks of a program
  ♦ All chunks are the same size
  ♦ Use valid bit to detect references to swapped pages
  ♦ Pages are a convenient multiple of the disk block size
Paging Limitations

• Can still have internal fragmentation
  ♦ Process may not use memory in multiples of a page

• Memory reference overhead
  ♦ 2 references per address lookup (page table, then memory)
  ♦ Solution – use a hardware cache of lookups (more later)

• Memory required to hold page table can be significant
  ♦ Need one PTE per page
  ♦ 32 bit address space w/ 4KB pages = \(2^{20}\) PTEs
  ♦ 4 bytes/PTE = 4MB/page table
  ♦ 25 processes = 100MB just for page tables!
  ♦ Solution – hierarchical page tables (more later)
Segmentation

- Segmentation is a technique that partitions memory into logically related data units
  - Module, procedure, stack, data, file, etc.
  - Virtual addresses become `<segment #, offset>`
    - x86 stores segment #s in registers (CS, DS, SS, ES, FS, GS)
  - Units of memory from programmer’s perspective

- Natural extension of variable-sized partitions
  - Variable-sized partitions = 1 segment/process
  - Segmentation = many segments/process

- Hardware support
  - Multiple base/limit pairs, one per segment (segment table)
  - Segments named by #, used to index into table

(aka Segment Fault)
Segment Table

- **Extensions**
  - Can have one segment table per process
    - Segment #s are then process-relative
  - Can easily share memory
    - Put same translation into base/limit pair
    - Can share with different protections (same base/limit, diff prot)

- **Problems**
  - Cross-segment addresses
    - Segments need to have same #s for pointers to them to be shared among processes
  - Large segment tables
    - Keep in main memory, use hardware cache for speed
  - Large segments
    - Internal fragmentation, paging to/from disk is expensive
Segmentation and Paging

- Can combine segmentation and paging
  - The x86 in 32-bit mode supports segments and paging
- Use segments to manage logically related units
  - Module, procedure, stack, file, data, etc.
  - Segments vary in size, but usually large (multiple pages)
- Use pages to partition segments into fixed size chunks
  - Makes segments easier to manage within physical memory
    - Segments become “pageable” – rather than moving segments into and out of memory, just move page portions of segment
  - Need to allocate page table entries only for those pieces of the segments that have themselves been allocated
- Tends to be complex…
Summary

• Virtual memory
  ♦ Processes use virtual addresses
  ♦ Hardware translates virtual address into physical addresses with OS support

• Various techniques
  ♦ Fixed partitions – easy to use, but internal fragmentation
  ♦ Variable partitions – more efficient, but external fragmentation
  ♦ Paging – use small, fixed size chunks, efficient for OS
  ♦ Segmentation – manage in chunks from user’s perspective
  ♦ Combine paging and segmentation to get benefits of both
