Virtual Machine Monitors

• Virtual Machine Monitors (VMMs) are a hot topic in industry and academia
  ♦ Industry commitment
    » Software: VMware, Xen, Microsoft Virtual PC
    » Hardware: Intel VT, AMD-V
      ▪ If Intel and AMD add it to their chips, you know it’s serious…
  ♦ Academia: lots of VMM-based projects and papers

• An old idea, actually: developed by IBM in 60s and 70s

• Today
  ♦ What is it, what problems have to be solved, how to solve them
  ♦ Survey some virtualization systems
What is a VMM?

- We have seen that an OS already virtualizes
  - Syscalls, processes, virtual memory, file system, sockets, etc.
  - Applications program to this interface
- A **VMM** virtualizes an entire physical machine
  - Interface supported is the hardware
    - In contrast, OS defines a higher-level interface
  - VMM provides the **illusion** that software has full control over the hardware (of course, VMM is in control)
  - VMM “applications” run in **virtual machines** (c.f., OS processes)
- Implications
  - You can boot an operating system in a virtual machine
  - Run multiple instances of an OS on same physical machine
  - Run different OSes simultaneously on the same machine
    - Linux on Windows, Windows on Mac, etc.
Why VMMs?

- **Resource utilization**
  - Machines today are powerful, want to multiplex their hardware
    - Cloud hosting can divvy up a physical machine to customers
  - Can migrate VMs from one machine to another without shutdown

- **Software use and development**
  - Can run multiple OSes simultaneously
    - No need to dual boot
  - Can do system (e.g., OS) development at user-level

- **Many other cool applications**
  - Debugging, emulation, security, speculation, fault tolerance…

- **Common theme is manipulating applications/services at the granularity of a machine**
  - Specific version of OS, libraries, applications, etc., as package
VMM Requirements

- **Fidelity**
  - OSes and applications work the same without modification
    - (although we may modify the OS a bit)

- **Isolation**
  - VMM protects resources and VMs from each other

- **Performance**
  - VMM is another layer of software...and therefore overhead
    - As with OS, want to minimize this overhead
  - VMware (early):
    - CPU-intensive apps: 2-10% overhead
    - I/O-intensive apps: 25-60% overhead (much, much better today)
Rough VMM Model

- VMM runs with privilege
  - OS in VM runs at “lesser” privilege (think user-level)
  - VMM multiplexes resources among VMs
- Want to run OS code in a VM directly on CPU
  - Think in terms of making the OS a user-level process
  - What OS code can run directly, what will cause problems?
- Ideally, want privileged instructions to trap
  - Exception vectors to VMM, it emulates operation, returns
  - Nothing modified, running unprivileged is transparent
  - Known as trap-and-emulate
- Unfortunately on architectures like x86, not so easy
Virtualizing the x86

- Ease of virtualization influenced by the architecture
  - x86 is perhaps the last architecture you would choose
  - But it’s what everyone uses, so…that’s what we deal with

- Issues
  - Unvirtualizable events
    » `popf` does not trap when it cannot modify system flags
  - Hardware-managed TLB
    » VMM cannot easily interpose on a TLB miss (more in a bit)
  - Untagged TLB
    » Have to flush on context switches (just a performance issue)

- Why Intel and AMD have added virtualization support
Xen

• Early versions use “paravirtualization”
  ♦ Fancy word for “we have to modify & recompile the OS”
  ♦ Since you’re modifying the OS, make life easy for yourself
  ♦ Create a VMM interface to minimize porting and overhead

• Xen hypervisor (VMM) implements interface
  ♦ VMM runs at privilege, VMs (domains) run unprivileged
  ♦ Trusted OS (Linux) runs in own domain (Domain0)
    » Use Domain0 to manage system, operate devices, etc.

• Most recent version of Xen does not require OS mods
  ♦ Because of Intel/AMD hardware support

• Commercialized via XenSource, but also open source
Xen Architecture

- Control Plane Software
  - GuestOS (XenoLinux)
    - Xeno-Aware Device Drivers
- User Software
  - GuestOS (XenoLinux)
    - Xeno-Aware Device Drivers
  - GuestOS (XenoBSD)
    - Xeno-Aware Device Drivers
  - GuestOS (XenoXP)
    - Xeno-Aware Device Drivers
- Domain0 control interface
- virtual x86 CPU
- virtual phy mem
- virtual network
- virtual blockdev

H/W (SMP x86, phy mem, enet, SCSI/IDE)
VMware

- VMware workstation uses **hosted** model
  - VMM runs unprivileged, installed on base OS (+ driver)
  - Relies upon base OS for device functionality
- VMware ESX server uses **hypervisor** model
  - Similar to Xen, but no guest domain/OS
- VMware uses **software virtualization**
  - Dynamic binary rewriting translates code executed in VM
    » Rewrite privileged instructions with emulation code (may trap)
  - CPU only executes translated code
  - Think JIT compilation for JVM, but
    » full binary x86 → IR code → safe subset of x86
  - Incurs overhead, but can be well-tuned (small % hit)

What needs to be virtualized?

• Exactly what you would expect
  ♦ CPU
  ♦ Events (exceptions and interrupts)
  ♦ Memory
  ♦ I/O devices

• Isn’t this just duplicating OS functionality in a VMM?
  ♦ Yes and no
  ♦ Approaches will be similar to what we do with OSes
    » Simpler in functionality, though (VMM much smaller than OS)
  ♦ But implements a different abstraction
    » Hardware interface vs. OS interface
Virtualizing Privileged Instrs

- OSes can no longer successfully execute privileged instructions
  - Virtual memory registers, interrupts, I/O, halt, etc.
- For those instructions that cause an exception
  - Trap to VMM, take care of business, return to OS in VM
- For those that do not…
  - **Xen**: modify OS to hypervisor call into VMM
  - **VMware**: rewrite OS instructions to emulate or call into VMM
  - **H/W support**: add new CPU mode, instructions to support trap and emulate
Virtualizing the CPU

• VMM needs to multiplex VMs on CPU
• How? Just as you would expect
  ♦ Timeslice the VMs
  ♦ Each VM will timeslice its OS/applications during its quantum
• Typically relatively simple scheduler
  ♦ Round robin, work-conserving (give unused quantum to other VMs)
Virtualizing Events

- VMM receives interrupts, exceptions
- Needs to vector to appropriate VM
  - **Xen**: modify OS to use virtual interrupt register, event queue
  - **VMware**: craft appropriate handler invocation, emulate event registers
Virtualizing I/O

- OSes can no longer interact directly with I/O devices
- **Xen**: modify OS to use low-level I/O interface *(hybrid)*
  - Define generic devices with simple interface
    - Virtual disk, virtual NIC, etc.
  - Ring buffer of control descriptors, pass pages back and forth
  - Handoff to trusted domain running OS with real drivers
- **VMware**: VMM supports generic devices *(hosted)*
  - E.g., AMD Lance chipset/PCNet Ethernet device
  - Load driver into OS in VM, OS uses it normally
  - Driver knows about VMM, cooperates to pass the buck to a real device driver (e.g., on underlying host OS)
- **VMware ESX Server**: drivers run in VMM *(hypervisor)*
Virtualized I/O Models

Abramson et al., “Intel Virtualization Technology for Directed I/O”, Intel Technology Journal, 10(3) 2006
Virtualizing Memory

- OSes assume they have full control over memory
  - Managing it: OS assumes it owns it all
  - Mapping it: OS assumes it can map any virtual page to any physical page

- But VMM partitions memory among VMs
  - VMM needs to assign hardware pages to VMs
  - VMM needs to control mappings for isolation
    - Cannot allow an OS to map a virtual page to any hardware page
    - OS can only map to a hardware page given to it by the VMM

- Hardware-managed TLBs make this difficult
  - When the TLB misses, the hardware automatically walks the page tables in memory
  - As a result, VMM needs to control access by OS to page tables
Xen Paravirtualization

• Xen uses the page tables that an OS creates
  ♦ These page tables are used directly by hardware MMU
• Xen validates all updates to page tables by OS
  ♦ OS can read page tables without modification
  ♦ But Xen needs to check all PTE writes to ensure that the virtual-to-physical mapping is valid
    » That the OS “owns” the physical page being used in the PTE
  ♦ Modify OS to hypervisor call into Xen when updating PTEs
    » Batch updates to reduce overhead

• Page tables work the same as before, but OS is constrained to only map to the physical pages it owns
• Works fine if you can modify the OS. If you can’t…
Shadow Page Tables

• Three abstractions of memory
  ♦ Machine: actual hardware memory
    » 16 GB of DRAM
  ♦ Physical: abstraction of hardware memory managed by OS
    » If a VMM allocates 512 MB to a VM, the OS thinks the computer has 512 MB of contiguous physical memory
    » (Underlying machine memory may be discontiguous)
  ♦ Virtual: virtual address spaces you know and love
    » Standard $2^{32}$ or $2^{64}$ address space

• In each VM, OS creates and manages page tables for its virtual address spaces without modification
  ♦ But these page tables are not used by the MMU hardware
Shadow Page Tables (2)

- VMM creates and manages page tables that map virtual pages directly to machine pages
  - These tables are loaded into the MMU on a context switch
  - VMM page tables are the shadow page tables
- VMM needs to keep its V→M tables consistent with changes made by OS to its V→P tables
  - VMM maps OS page tables as read only
  - When OS writes to page tables, trap to VMM
  - VMM applies write to shadow table and OS table, returns
  - Also known as memory tracing
  - Again, more overhead…
Shadow Page Tables (3)

[Diagram showing the mapping of guest and machine memory pages for two guests, A and B, with virtual and physical address spaces.]
Memory Allocation

- VMMs tend to have simple hardware memory allocation policies
  - Static: VM gets 512 MB of hardware memory for life
  - No dynamic adjustment based on load
  - No swapping to disk
- More sophistication: Overcommit with balloon driver
  - Balloon driver runs inside OS to consume hardware pages
  - Steals from virtual memory and file buffer cache (balloon grows)
  - Gives hardware pages to other VMs (those balloons shrink)
- Identify identical physical pages (e.g., all zeroes)
  - Map those pages copy-on-write across VMs
Hardware Support

• Intel and AMD implement virtualization support in their recent x86 chips (Intel VT-x, AMD-V)
  ♦ Goal is to fully virtualize architecture
  ♦ Transparent trap-and-emulate approach now feasible
  ♦ Echoes hardware support originally implemented by IBM

• Execution model
  ♦ New execution mode: guest mode
    » Direct execution of guest OS code, including privileged insts
  ♦ Virtual machine control block (VMCB)
    » Controls what operations trap, records info to handle traps in VMM
  ♦ New instruction \texttt{vmenter} enters guest mode, runs VM code
  ♦ When VM traps, CPU executes new \texttt{vmexit} instruction
  ♦ Enters VMM, which emulates operation
Hardware Support (2)

• Memory
  ♦ Intel extended page tables (EPT), AMD nested page tables (NPT)
  ♦ Original page tables map virtual to (guest) physical pages
    » Managed by OS in VM, backwards-compatible
    » No need to trap to VMM when OS updates its page tables
  ♦ New tables map physical to machine pages
    » Managed by VMM
  ♦ Tagged TLB w/ virtual process identifiers (VPIDs)
    » Tag VMs with VPID, no need to flush TLB on VM/VMM switch

• I/O
  ♦ Constrain DMA operations only to page owned by specific VM
  ♦ AMD DEV: exclude pages (c.f. Xen memory paravirtualization)
  ♦ Intel VT-d: IOMMU – address translation support for DMA
Summary

• VMMs multiplex virtual machines on hardware
  ♦ Export the hardware interface
  ♦ Run OSes in VMs, apps in OSes unmodified
  ♦ Run different versions, kinds of OSes simultaneously

• Lesson: Never underestimate the power of indirection
