Announcements

• Assignment 1 will be released today
  – Due Oct 5, 11:59 PM

• Educational research studies
  – Pre-test today, last 20 minutes of lecture meeting
  – Sep 30, weekly survey (if study starts this week)

• Reading:
  – Liang
    • Chapters 1 and 2
Programs

• Computer programs (i.e., software) are instructions to the computer
• You tell a computer what to do through programs
• Computers do not understand human languages, so you need to use computer languages to communicate with them
• Programs are written using programming languages
Programming languages

- Machine language
- Assembly language
- High-level language
Programming languages

• Machine language
  – Machine language is a set of primitive instructions built into every computer
  – The instructions are in the form of binary code, so you must enter binary codes for various instructions
  – Programming with native machine language is a tedious process, and the programs are highly difficult to read and modify
  – For example, to add two numbers, you might write an instruction in binary like this:
    1101101010011010
Programming languages

• Assembly language
  – Assembly languages were developed to make programming easier than machine languages
  – Since the computer cannot understand assembly language, a program called assembler is used to convert assembly language programs into machine code
  – For example, to add two numbers, you might write an instruction in assembly code like this:
    ADDF3 R1, R2, R3
Programming languages

• High-level language
  – High-level languages are English-like and easier to learn and program than assembly languages
  • For example, the following is a high-level language statement that computes the area of a circle with radius 5:
    \[
    \text{area} = 5 \times 5 \times 3.1415;
    \]
Interpreting/Compiling source code

• A program written in a high-level language is called a source program or source code
• Because a computer cannot understand a source program, a source program must be translated into machine code for execution
• The translation can be done using another programming tool called an interpreter or a compiler
Interpreting source code

• An interpreter reads one statement from the source code, translates it to the machine code or virtual machine code, and then executes it right away

• A statement from the source code may be translated into several machine instructions
Compiling source code

- A compiler translates the entire source code into a machine-code file, and the machine-code file is then executed.
Java

• The **compiler** of Java is called **javac**
  – Java source code is compiled into the Java Virtual Machine (JVM) code called bytecode

• The **interpreter** of Java is called **java**
  – The bytecode is machine-independent and can run on any machine that has a Java interpreter, which is part of the JVM (write once, run anywhere)
Java

• Java is a high-level language
• Java is a general-purpose programming language
• Java can be used to develop standalone applications
• Java can be used to develop applications for web servers
Anatomy of a Java program

- Class name
- Main method
- Statements
- Statement terminator
- Reserved words
- Comments
- Blocks
Class name

• Every Java program must have at least one class
• Each class has a name
• Naming convention: capitalize the first letter of each word in the name class (e.g., ComputeArea)
• This class name is Welcome

// This program prints Welcome to Java!
public class Welcome {
    public static void main(String[] args) {
        System.out.println("Welcome to Java!");
    }
}

CSE 8B, Fall 2022
In order to run a class, the class must contain a method named main.

The program is executed from the main method.

This line defines the main method:

```java
// This program prints Welcome to Java!
public class Welcome {
    public static void main(String[] args) {
        System.out.println("Welcome to Java!");
    }
}
```
Statement

• A statement represents an action or a sequence of actions

• This is a statement to display the greeting “Welcome to Java!”

```java
// This program prints Welcome to Java!
public class Welcome {
    public static void main(String[] args) {
        System.out.println("Welcome to Java!");
    }
}
```
println and print

println

public void println(String x)

Prints a String and then terminate the line. This method behaves as though it invokes print(String) and then println().

Parameters:
x - The String to be printed.

print

public void print(String s)

Prints a string. If the argument is null then the string "null" is printed. Otherwise, the string's characters are converted into bytes according to the platform's default character encoding, and these bytes are written in exactly the manner of the write(int) method.

Parameters:
s - The String to be printed

println

public void println()

Terminates the current line by writing the line separator string. The line separator string is defined by the system property line.separator, and is not necessarily a single newline character ('\n').
Java Application Programming Interface (API) Documentation

• Documentation for all Java built-in classes and methods

• Java 8 API Documentation
  https://docs.oracle.com/javase/8/docs/api/

• Java 11 API Documentation
  https://docs.oracle.com/en/java/javase/11/docs/api/

• Use the documentation!
Statement terminator

• Every statement in Java ends with a semicolon

```java
// This program prints Welcome to Java!
public class Welcome {
    public static void main(String[] args) {
        System.out.println("Welcome to Java!");
    }
}
```
Reserved words

• Reserved words or keywords are words that have a specific meaning to the compiler and cannot be used for other purposes in the program
• For example, when the compiler sees the word class, it understands that the word after class is the name for the class

```java
// This program prints Welcome to Java!
public class Welcome {
   public static void main(String[] args) {
      System.out.println("Welcome to Java!");
   }
}
```
Comments

- Comments make the code more readable by adding details
- Implementation comments are meant for commenting out code or for comments about the particular implementation
- // comments out everything after it on the line
- The comment delimiters /*...*/ comments out everything between /* and */

```java
// This program prints Welcome to Java!
public class Welcome {
    public static void main(String[] args) {
        System.out.println("Welcome to Java!");
    }
}
```
Blocks

• A pair of braces in a program forms a block that groups components of a program

public class Test {
  public static void main(String[] args) {
    System.out.println("Welcome to Java!");
  }
}
Blocks

• Two different block styles

```java
public class Test {
  public static void main(String[] args) {
    System.out.println("Block Styles");
  }
}
```

Corresponding braces are column-aligned

First and last lines of block are column-align

Next-line style

End-of-line style
# Special symbols

<table>
<thead>
<tr>
<th>Character Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>{}</td>
<td>Opening and closing braces. Denotes a block to enclose statements.</td>
</tr>
<tr>
<td>()</td>
<td>Opening and closing parentheses. Used with methods.</td>
</tr>
<tr>
<td>[]</td>
<td>Opening and closing brackets. Denotes an array.</td>
</tr>
<tr>
<td>//</td>
<td>Double slashes. Precedes a comment line.</td>
</tr>
<tr>
<td>&quot; &quot;</td>
<td>Opening and closing quotation marks. Enclosing a string (i.e., sequence of characters).</td>
</tr>
<tr>
<td>;</td>
<td>Semicolon. Marks the end of a statement.</td>
</tr>
</tbody>
</table>
Identifiers

- Identifiers are the **names** that identify the elements such as **classes, methods, and variables** in a program.
- An identifier is a sequence of characters that consist of letters, digits, underscores (\_), and dollar signs ($)
- An identifier must start with a letter, an underscore (\_), or a dollar sign ($)
- An identifier cannot start with a digit
- An identifier cannot be a reserved word
  - List of reserved words
    - Liang, Appendix A
    - [https://docs.oracle.com/javase/tutorial/java/nutsandbolts/_keywords.html](https://docs.oracle.com/javase/tutorial/java/nutsandbolts/_keywords.html)
- An identifier cannot be **true**, **false**, or **null**
- An identifier can be of any length
Variable and method names

• Naming convention: Use lowercase. If the name consists of several words, concatenate all in one, use lowercase for the first word, and capitalize the first letter of each subsequent word in the name
  – For example, the variables $radius$ and $area$, and the method $computeArea$. 
Variables

- Variables are used to represent values that may be changed in the program

```java
// Compute the first area
radius = 1.0;
area = radius * radius * 3.14159;
System.out.println("The area is " + area + " for radius " + radius);

// Compute the second area
radius = 2.0;
area = radius * radius * 3.14159;
System.out.println("The area is " + area + " for radius " + radius);
```
Declaring variables

```c
int x;       // Declare x to be an
            // integer variable
double radius; // Declare radius to
               // be a double variable
char a;      // Declare a to be a
            // character variable
```
Assignment statements

x = 1;       // Assign 1 to x
radius = 1.0; // Assign 1.0 to radius
a = 'A';     // Assign 'A' to a
Declaring and initializing in one step

```c
int x = 1;
double radius = 1.0;
char a = 'A';
```
Named constants

• Naming convention: capitalize all letters in constants, and use underscores to connect words

```java
final datatype CONSTANTNAME = VALUE;
final double PI = 3.14159;
final int MAX_VALUE = 3;
final char FIRST_UPPER_CASE = 'A';
```
public class ComputeArea {
    /** Main method */
    public static void main(String[] args) {
        double radius;
        double area;

        // Assign a radius
        radius = 20;

        // Compute area
        area = radius * radius * 3.14159;

        // Display results
        System.out.println("The area for the circle of radius "+
                           radius + "+ area);
    }
}

Documentation (or doc or Javadoc) comments
• The comment delimiters /*...*/ comments out everything between /* and */, including the * following the begin delimiter */
• /** indicates this is beginning of a doc comment
public class ComputeArea {
    /** Main method */
    public static void main(String[] args) {
        double radius;
        double area;

        // Assign a radius
        radius = 20;

        // Compute area
        area = radius * radius * 3.14159;

        // Display results
        System.out.println("The area for the circle of radius " +
                          radius + " is " + area);
    }
}
Trace a program execution

```java
public class ComputeArea {
    /** Main method */
    public static void main(String[] args) {
        double radius;
        double area;

        // Assign a radius
        radius = 20;

        // Compute area
        area = radius * radius * 3.14159;

        // Display results
        System.out.println("The area for the circle of radius " + radius + " is " + area);
    }
}
```
public class ComputeArea {
    /** Main method */
    public static void main(String[] args) {
        double radius;
        double area;

        // Assign a radius
        radius = 20;

        // Compute area
        area = radius * radius * 3.14159;

        // Display results
        System.out.println("The area for the circle of radius " +
                           radius + " is " + area);
    }
}
public class ComputeArea {
    /** Main method */
    public static void main(String[] args) {
        double radius;
        double area;

        // Assign a radius
        radius = 20;

        // Compute area
        area = radius * radius * 3.14159;

        // Display results
        System.out.println("The area for the circle of radius "+
                           radius + " is "+ area);
    }
}
public class ComputeArea {
    /** Main method */
    public static void main(String[] args) {
        double radius;
        double area;

        // Assign a radius
        radius = 20;

        // Compute area
        area = radius * radius * 3.14159;

        // Display results
        System.out.println("The area for the circle of radius "+radius+" is "+area);
    }
}
Developing, compiling, and running Java programs

public class Welcome {
    public static void main(String[] args) {
        System.out.println("Welcome to Java!");
    }
}

Welcome.java

Source code (developed by the programmer)

Welcome.class

Bytecode (generated by the compiler for JVM to read and interpret)

... Method Welcome()
  0 anew-array
  2 astore_0
...

Method void main(java.lang.String[])
  0 getstatic #2 ...
  3 ldc #3 <String "Welcome to Java!">
  5 invokevirtual #4 ...
  8 return

“Welcome to Java” is displayed on the console

Welcome to Java!
Programming errors

• Syntax errors
  – Detected by the compiler
    • The **compiler** of Java is called **javac**

• Runtime errors
  – Causes the program to abort
    • The **interpreter** of Java is called **java**

• Logic errors
  – Produces incorrect result
Syntax errors

• If you mistype part of a program, the compiler may issue a syntax error. The message usually displays the type of the error, the line number where the error was detected, the code on that line, and the position of the error within the code.

• For example, following is an error caused by omitting a semicolon at the end of a statement:

```
Testing.java:8: error: ';' expected
  count++
  ^
1 error
```

• If you see any compiler errors, then your program did not successfully compile, and the compiler did not create a .class file. Carefully verify the program, fix any errors that you detect, and try again.
Syntax errors

• Semantic Errors: In addition to verifying that your program is syntactically correct, the compiler checks for other basic correctness. For example, the compiler warns you each time you use a variable that has not been initialized.

Testing.java:8: error: variable count might not have been initialized
    count++;
   ^ Position of the error within the code

Testing.java:9: error: variable count might not have been initialized
    System.out.println("Input has " + count + " chars.");
   ^ Position of the error within the code

2 errors

• Again, your program did not successfully compile, and the compiler did not create a .class file. Fix the error and try again.
Runtime errors

Exception in thread "main"

• If you encounter this, see
  https://docs.oracle.com/javase/tutorial/getStarted/problems/index.html#interpreter
Next Lecture

• Mathematical functions, characters, and strings
