

## 5. Divide-and-Conquer

Not in book: Quicksort

How?

Quicksort

Divide:

- Choose  $e$  from input  $A$
- Partition  $A$  into  $A^-$ ,  $e$ , and  $A^+$

Conquer:

- Quicksort( $A^-$ )
- Quicksort( $A^+$ )

Combine:

- Output sorted  $A^-$ , then  $e$ , then sorted  $A^+$

Mergesort: easy divide, hard combine

Quicksort: hard divide, easy combine

## Quicksort pseudo-code

Precondition:  $A$  an array of elements

Quicksort( $A$ )

if  $|A| \leq 1$

return  $A$  base case

Choose a splitter  $a_i$  from  $A$

$A^- = A^+ = \{\}$

foreach element  $a_j$  of  $A$  do

LI:  $A^- \cup A^+ \cup a_j = A$  and  $e \in A^- \leq a_j$  and  $e \in A^+ \geq a_j$

if  $a_j < a_i$  then

Add  $a_j$  to  $A^-$

else

Add  $a_j$  to  $A^+$

end foreach

Assert:  $e \in A^- \leq a_j$ ;  $e \in A^+ \geq a_j$

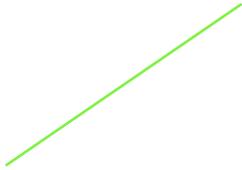

Quicksort( $A^-$ ) Assert:  $A^-$  in sorted order (inductive hyp.)

Quicksort( $A^+$ ) Assert:  $A^+$  in sorted order (inductive hyp.)

Return  $A^-$  followed by  $a_i$  followed by  $A^+$

Precondition: Returns  $A$  in sorted order

Partition

## Quicksort in-place pseudo-code

Precondition:  $A[l..r]$  is sub-array of items

procedure Quicksort( $A, l, r$ )

if  $l + 1 \geq r$

return  $A$

Choose a splitter  $a_i$  from  $A[l..A[r]$

$k = \text{Partition}(A, l, r, j)$

Quicksort( $A, l, k-1$ )

$A^- = A[l..k-1]$

Quicksort( $A, k+1, r$ )

$A^+ = A[k+1..r]$

Postcondition:  $A[l..r]$  contains original elements in sorted order

Index where splitter was put

## Partition pseudo-code

Precondition:  $A[l..r]$  is sub-array of items.  $j$  is in range  $[l..r]$

```
function Partition(A, l, r, j)
```

```
  Swap(A[j], A[r])
```

```
  ll = rr = i = l-1;
```

```
  loop    LI:  $A[l..ll] \leq A[r]$ ,  $A[rr..i] \geq A[r]$   $A[l..r]$  contains original elements of A
```

```
    LI:  $A[l..ll] \leq A[r]$ ,  $A[rr..i] \geq A[r]$   $A[l..r]$  contains original elements of A
```

```
    exit when  $i = r$ 
```

```
     $i = i+1$ ;
```

```
    if  $A[i] < A[r]$  then
```

```
      Swap(A[rr], A[i])
```

```
       $rr = rr + 1$ ;
```

```
       $ll = ll + 1$ ;
```

```
  endloop  Assert:  $A[l..r]$  contains original elements of A.
```

```
     $A[l..ll] \leq A[r]$ ,  $A[rr..r-1] \geq A[r]$ 
```

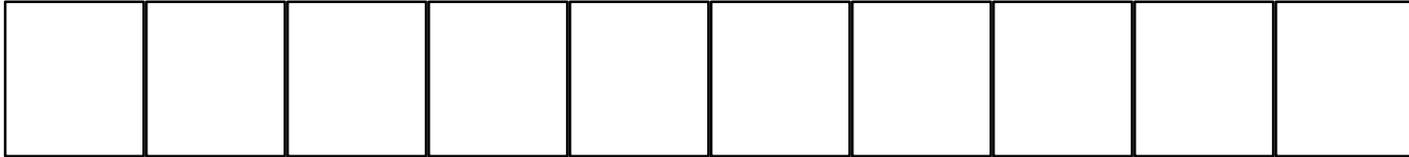

```
  Swap(A[r], A[rr]);
```

```
  Return  $k = rr$ .
```

Postcondition:  $A[l..r]$  contains original elements of A.

Returns  $k$  s.t.  $A[l..k-1] \leq A[k] (=A[j]) \leq A[k+1]..A[r]$

## In-place quicksort in action

## Runtime analysis of Quicksort

What is  $T(n)$ ?

Divide: Partition:  $O(n)$

Conquer:  $\max(\$

$$T(1) + T(n-2)$$

$$T(2) + T(n-3)$$

...

$$T(n-2) + T(1))$$

$$T(n) = T(n-1) + O(n)$$

$$T(n) = T(n-2) + O(n) + O(n)$$

$$T(n) = T(1) + (n-2) * O(n)$$

$$T(n) = O(n^2)$$

Combine:  $O(1)$

Worst case:  $O(n^2)$

Worst-case input?

# Quicksort

## How to choose the splitter

- First
- Last
- Middle
- Best of three
- Random
- Best of best of three

## Average-case complexity of Quicksort

### Observations:

- After an element  $a_i$  is chosen as a splitter value and compared to other elements in its range, it is never compared again
- If two elements are separated into different partitions, they will never be compared to each other again

If we look at a range of sorted elements  $z_i..z_j$ ,  $z_i$  and  $z_j$  are compared to each other only if  $z_i$  or  $z_j$  chosen as a splitter before any elements between  $z_i$  and  $z_j$

## Average-case complexity of Quicksort

Let  $x$  and  $y$  be two elements with  $x \leq y$

- If Quicksort picks any splitter  $z$  with  $x \leq y \leq z$  before it picks  $x$  or  $y$  then it never compares  $x$  to  $y$
- Assume that it picks the splitters randomly from all candidates in an unpartition group
- If  $x$  and  $y$  are  $k$  places apart in the final sorted order, the chance of picking  $x$  or  $y$  before picking  $z$  between them is  $2/(k+1)$

The farther apart two elements in the final order, the less likely they are to be compared

## Average-case complexity for Quicksort

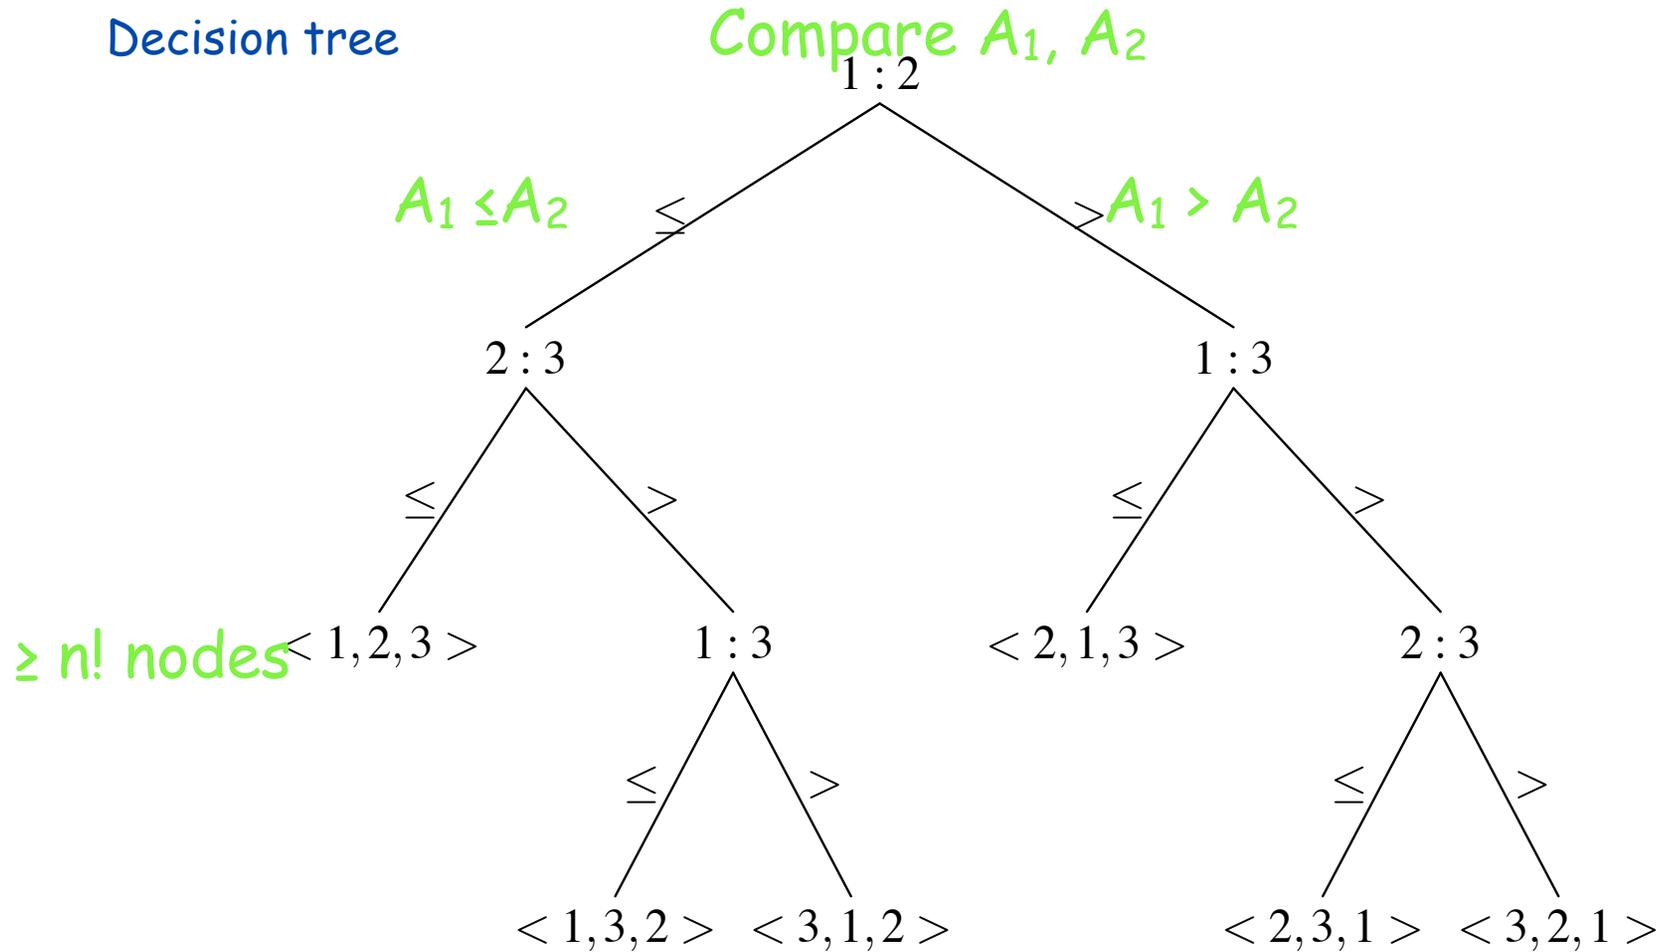

"If x and y are k places apart in the final sorted order, the chance of picking x or y before picking z between them is  $2/(k+1)$ "

1 pair	n-1 apart	$1 \cdot (2/n)$	$= \sum_{i=1}^{n-1} \sum_{k=1}^{n-i} \frac{2}{k+1}$
2 pairs	n-2 apart	$2 \cdot (2/(n-1))$	$\leq \sum_{i=1}^n \sum_{k=1}^n \frac{2}{k}$
3 pairs	n-3 apart		
...			
n-2 pairs	2 apart	$(n-2) \cdot (2/3)$	
n-1 pairs	1 apart	$(n-1) \cdot (2/2)$	
		<hr/>	
		$\theta(n \log n)$	$\leq \sum_{i=1}^n \sum_{k=1}^n \frac{2}{k} = 2(\log n + 1) = O(n \log n)$

Averaged across all \_\_\_\_\_ inputs, Quicksort takes time  $\theta(n \log n)$

# Lower bound for comparison-based sorting

Decision tree

Sorted order  
is  $A_1, A_3, A_2$

Model ANY sorting alg based on  
compares as decision tree

## Lower-bound for comparison based sorting

Min height of tree with  $k$  leaves =  $\log k$

Min height of tree with  $n!$  leaves =  $\log(n!)$

$$= \theta(n \log n)$$

## Lower-bound for comparison-based sorting

Any algorithm based on comparisons between elements is in  $\Omega(n \log n)$  time

For any algorithm, there's an instance that takes at least  $n \log n$

Can there be algorithms with instances that sort in  $O(n)$  time?

Can there be algorithms that sort in  $O(n \log n)$  time for every instance?

Can there be algorithms that sort in  $O(n \log n)$  time for most instances?
