Lecture 18: Interdomain routing
Border Gateway Protocol

CSE 123: Computer Networks

Lecture 18 Overview

- Path vector routing
- Border Gateway Protocol (BGP)
  - The canonical path vector protocol
  - How routing gets done on the Internet today
- AS relationships
  - Customer/Provider
  - Multihoming
  - Peer-to-peer
Autonomous Systems

- Internet is divided into Autonomous Systems
  - Distinct regions of administrative control
  - Routers/links managed by a single “institution”
  - Service provider, company, university, …

- Hierarchy of Autonomous Systems
  - Large, “tier-1” provider with a nationwide backbone
  - Medium-sized regional provider with smaller backbone
  - Small network run by a single company or university

- Interaction between Autonomous Systems
  - Internal topology is not shared between ASes
  - … but, neighboring ASes interact to coordinate routing
Border routers summarize and advertise their routes to external neighbors and vice-versa.
- Border routers apply policy.

Internal routers can use notion of default routes.

Core is default-free; routers must have a route to all networks in the world.

But what routing protocol?

---

CSE 123 – Lecture 18: Interdomain Routing
Issues with Link-state

- Topology information is flooded
  - High bandwidth and storage overhead
  - Forces nodes to divulge sensitive information

- Entire path computed locally per node
  - High processing overhead in a large network

- Minimizes some notion of total distance
  - Works only if policy is shared and uniform

- Typically used only inside an AS
  - E.g., OSPF and IS-IS
Advantages

- Hides details of the network topology
- Nodes determine only “next hop” toward the destination

Disadvantages

- Minimizes some notion of total distance, which is difficult in an interdomain setting
- Slow convergence due to the counting-to-infinity problem (“bad news travels slowly”)

Idea: extend the notion of a distance vector

- To make it easier to detect loops
Path-vector Routing

- Extension of distance-vector routing
  - Support flexible routing policies
  - Avoid count-to-infinity problem
- Key idea: advertise the entire path
  - Distance vector: send distance metric per destination
  - Path vector: send the entire path for each destination
Loop Detection

- Node can easily detect a loop
  - Look for its own node identifier in the path
  - E.g., node 1 sees itself in the path “3, 2, 1”
- Node can simply discard paths with loops
  - E.g., node 1 simply discards the advertisement
Each node can apply local policies
- Path selection: Which path to use?
- Path export: Which paths to advertise?

Examples
- Node 2 may prefer the path “2, 3, 1” over “2, 1”
- Node 1 may not let node 3 hear the path “1, 2”
Border Gateway Protocol

- Interdomain routing protocol for the Internet
  - Prefix-based path-vector protocol
  - Policy-based routing based on AS Paths
  - Evolved during the past 28 years

- 1989: BGP-1 [RFC 1105], replacement for EGP
- 1990: BGP-2 [RFC 1163]
- 1991: BGP-3 [RFC 1267]
- 1995: BGP-4 [RFC 1771], support for CIDR
- 2006: BGP-4 [RFC 4271], update
Basic BGP Operation

Establish session

Exchange all active routes

Exchange incremental updates

BGP session between Neighbors (TCP)

While connection is ALIVE exchange route UPDATE messages
A router learns multiple paths to destination
- Stores all of the routes in a routing table
- Applies policy to select a single active route
- ... and may advertise the route to its neighbors

Incremental updates
- Announcement
  » Upon selecting a new active route, add own AS to path
  » ... and (optionally) advertise to each neighbor
- Withdrawal
  » If the active route is no longer available
  » ... send a withdrawal message to the neighbors
A Simple BGP Route

- Destination prefix (e.g., 128.112.0.0/16)
- Route attributes, including
  - AS path (e.g., “7018 88”)
  - Next-hop IP address (e.g., 12.127.0.121)
(some) BGP Attributes

- **AS path**: ASs the announcement traversed
- **Next-hop**: where the route was heard from
- **Origin**: Route came from IGP or EGP
- **Local pref**: Statically configured ranking of routes within AS
- **Multi Exit Discriminator**: preference for where to exit network
- **Community**: opaque data used for inter-ISP policy
For Next Time
