

# Inheritance

Introduction to Programming and  
Computational Problem Solving:  
Accelerated Pace

CSE 11

Lecture 12

# Announcements

- Assignment 5 is due May 15, 11:59 PM
  - Upgrade beginning May 18, 12:01 AM
- Assignment 6 will be released May 15
  - Due May 22, 11:59 PM

# Inheritance

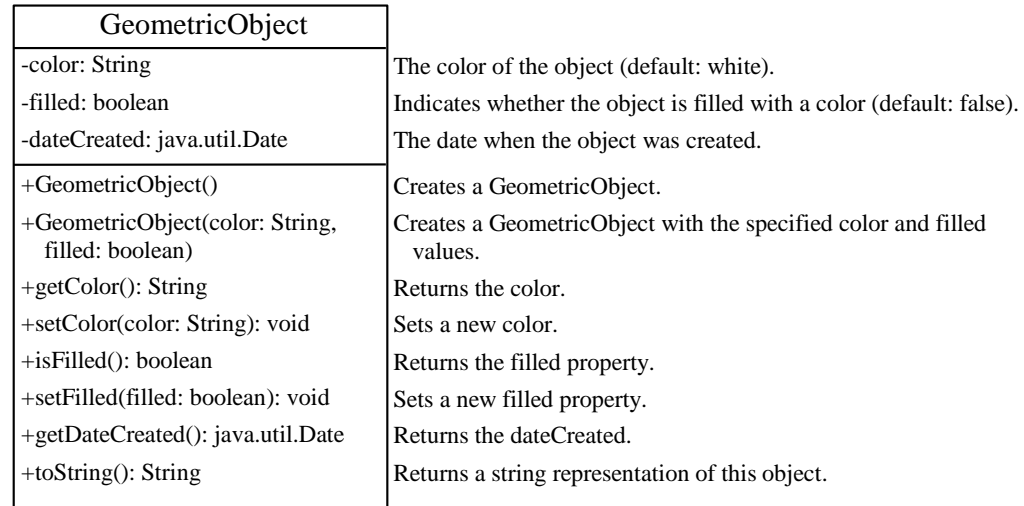

- Suppose you define classes to model circles, rectangles, and triangles
- These classes have many common features
- What is the best way to design these classes so to avoid redundancy?
- Object-oriented programming allows you to define new classes from existing classes
- This is called *inheritance*

# Superclasses and subclasses

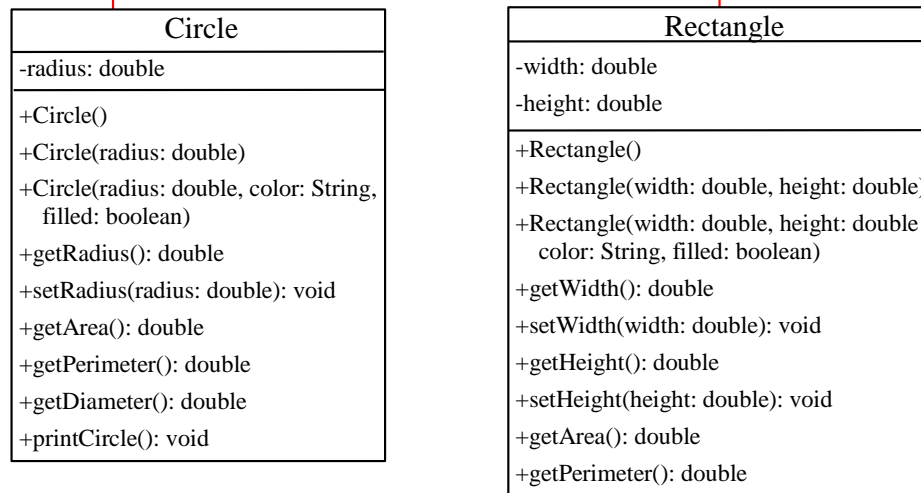

- Inheritance enables you to define a general class (i.e., a *superclass*) and later extend it to more specialized classes (i.e., *subclasses*)
- A subclass inherits from a superclass
  - For example, both a circle and a rectangle are geometric objects
    - `GeometricObject` is a superclass
    - `Circle` is a subclass of `GeometricObject`
    - `Rectangle` is a subclass of `GeometricObject`
- Models **is-a** relationships
  - For example
    - `Circle` **is-a** `GeometricObject`
    - `Rectangle` **is-a** `GeometricObject`

# Superclasses and subclasses

Superclass

Subclasses

# Superclasses and subclasses

- A subclass *inherits* accessible data fields and methods from its superclass and may also add *new* data fields and methods
  - **A subclass is not a subset of its superclass**
    - A subclass usually contains *more* information and methods than its superclass
  - For example
    - A rectangle has a width and height
    - A circle has a radius
    - Both have a color

# Superclasses and subclasses

- A **superclass** is also called a *parent class* or *base class*
- A **subclass** is also called a *child class*, *extended class*, or *derived class*
  - A child class inherits from a parent class
  - A subclass extends a superclass
  - A derived class derives from a base class

# Superclasses and subclasses

- Remember, a class defines a type
- A type defined by a subclass is called a *subtype*, and a type defined by its superclass is called a *supertype*
  - For example
    - Circle is a subtype of GeometricObject, and GeometricObject is a supertype for Circle

# Inheritance

- The keyword `extends` tells the compiler that the (sub)class extends another (super)class
- A Java class may inherit directly from only one superclass
  - This restriction is known as *single inheritance*
  - Some other programming languages allow classes to inherit from one or more classes
    - This is known as *multiple inheritance*

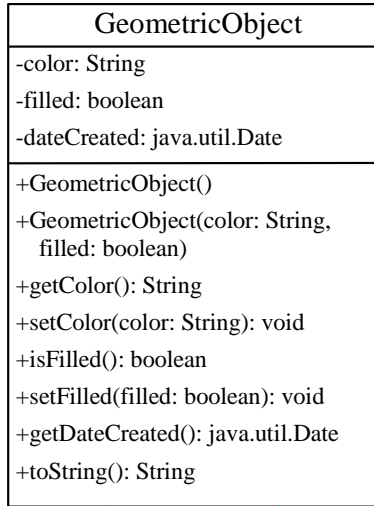

# extends keyword

- The keyword `extends` tells the compiler that the (sub)class extends another (super)class
- For example
  - The `Circle` class extends the `GeometricObject` class using the syntax  

```
public class Circle extends GeometricObject
```
  - The `Circle` class inherits the **accessible** data fields and methods of `GeometricObject`

# Circle extends GeometricObject

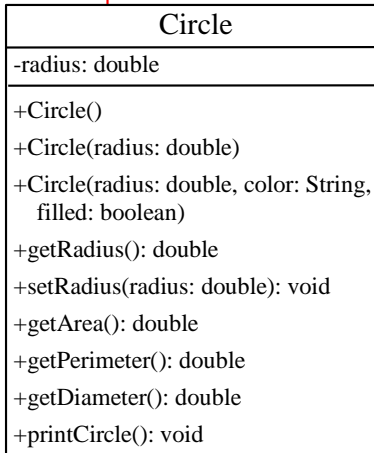

Superclass

The color of the object (default: white).  
Indicates whether the object is filled with a color (default: false).  
The date when the object was created.  
Creates a GeometricObject.  
Creates a GeometricObject with the specified color and filled values.  
Returns the color.  
Sets a new color.  
Returns the filled property.  
Sets a new filled property.  
Returns the dateCreated.  
Returns a string representation of this object.

Subclass

```
public class Circle extends GeometricObject {  
    private double radius;  
  
    public Circle() {  
    }  
  
    public Circle(double radius) {  
        this.radius = radius;  
    }  
}
```

# Unified Modeling Language (UML)

+ public

# protected

- private

- Static variables and methods are underlined
- Abstract class names and methods are *italicized*
- Interface names and methods are *italicized*
- Open or no arrow is association
- Hollow diamond is aggregation
- Filled diamond is composition
- Hollow triangle is inheritance
- Dashed line with hollow triangle is implementation of interface

| Modifiers on Members in a Class | Accessed from the Same Class | Accessed from the Same Package | Accessed from a Subclass in a Different Package | Accessed from a Different Package |
|---------------------------------|------------------------------|--------------------------------|---|-----------------------------------|
| Public                          | ✓                            | ✓                              | ✓   | ✓                                 |
| Protected                       | ✓                            | ✓                              | ✓   |                                   |
| Default (no modifier)           | ✓                            | ✓                              |   |                                   |
| Private                         | ✓                            |                                |   |                                   |

# Methods and data fields visibility

- **Private members cannot be accessed outside of a class, including one of its subclasses**
  - Use accessor (getter) and mutator (setter) methods

```
public class Circle extends GeometricObject {
    private double radius;

    public Circle() {
    }

    public Circle(double radius) {
        this.radius = radius;
    }

    public Circle(double radius, String color, boolean filled) {
        this.radius = radius;
        setColor(color);
        setFilled(filled);
    }
}
```

# Superclass constructors and the super keyword

- Remember, a constructor is used to construct an instance of a class
- Unlike properties and methods, **a superclass's constructors are not inherited in the subclass**
- They can only be invoked from the subclasses' constructors, using the keyword super
- **If the keyword super is not explicitly used, the superclass's no-arg constructor is automatically invoked**

# Superclass constructors and the super keyword

- For example, replace this

```
public class Circle extends GeometricObject {
    private double radius;

    public Circle(double radius, String color, boolean filled) {
        this.radius = radius;
        setColor(color);
        setFilled(filled);
    }
}
```

with this

```
public class Circle extends GeometricObject {
    private double radius;

    public Circle(double radius, String color, boolean filled) {
        super(color, filled);
        this.radius = radius;
    }
}
```

Invoking the superclass constructor using super must be the first statement in the subclass's constructor

# Superclass constructors and the super keyword

- If the keyword `super` is not explicitly used, the superclass's no-arg constructor is automatically invoked (as the **first** statement in the constructor)

# Constructor chaining

- Constructing an instance of a class invokes **all** the superclasses' constructors along the inheritance chain
- This is known as *constructor chaining*

# Constructor chaining

```
public class Faculty extends Employee {
    public static void main(String[] args) {
        new Faculty();
    }

    public Faculty() {
        System.out.println("(4) Faculty's no-arg constructor is invoked");
    }
}

class Employee extends Person {
    public Employee() {
        this("(2) Invoke Employee's overloaded constructor");
        System.out.println("(3) Employee's no-arg constructor is invoked");
    }

    public Employee(String s) {
        System.out.println(s);
    }
}

class Person {
    public Person() {
        System.out.println("(1) Person's no-arg constructor is invoked");
    }
}
```

# Trace code

```
public class Faculty extends Employee {  
    public static void main(String[] args) {  
        new Faculty();  
    }  
  
    public Faculty() {  
        System.out.println("(4) Faculty's no-arg constructor is invoked");  
    }  
}  
  
class Employee extends Person {  
    public Employee() {  
        this("(2) Invoke Employee's overloaded constructor");  
        System.out.println("(3) Employee's no-arg constructor is invoked");  
    }  
  
    public Employee(String s) {  
        System.out.println(s);  
    }  
}  
  
class Person {  
    public Person() {  
        System.out.println("(1) Person's no-arg constructor is invoked");  
    }  
}
```

1. Start from the main method

# Trace code

```
public class Faculty extends Employee {
    public static void main(String[] args) {
        new Faculty();
    }

    public Faculty() {
        System.out.println("(4) Faculty's no-arg constructor is invoked");
    }
}

class Employee extends Person {
    public Employee() {
        this("(2) Invoke Employee's overloaded constructor");
        System.out.println("(3) Employee's no-arg constructor is invoked");
    }

    public Employee(String s) {
        System.out.println(s);
    }
}

class Person {
    public Person() {
        System.out.println("(1) Person's no-arg constructor is invoked");
    }
}
```

2. Invoke Faculty constructor

# Trace code

```
public class Faculty extends Employee {
    public static void main(String[] args) {
        new Faculty();
    }

    public Faculty() {
        System.out.println("(4) Faculty's no-arg constructor is invoked");
    }
}

class Employee extends Person {
    public Employee() {
        this("(2) Invoke Employee's overloaded constructor");
        System.out.println("(3) Employee's no-arg constructor is invoked");
    }

    public Employee(String s) {
        System.out.println(s);
    }
}

class Person {
    public Person() {
        System.out.println("(1) Person's no-arg constructor is invoked");
    }
}
```

3. Invoke Employee's no-arg constructor

# Trace code

```
public class Faculty extends Employee {  
    public static void main(String[] args) {  
        new Faculty();  
    }  
}
```

```
public Faculty() {  
    System.out.println("(4) Faculty's no-arg constructor is invoked");  
}
```

```
class Employee extends Person {  
    public Employee() {  
        this("(2) Invoke Employee's overloaded constructor");  
        System.out.println("(3) Employee's no-arg constructor is invoked");  
    }  
}
```

```
public Employee(String s) {  
    System.out.println(s);  
}
```

```
class Person {  
    public Person() {  
        System.out.println("(1) Person's no-arg constructor is invoked");  
    }  
}
```

4. Invoke Employee(String) constructor

# Trace code

```
public class Faculty extends Employee {  
    public static void main(String[] args) {  
        new Faculty();  
    }  
  
    public Faculty() {  
        System.out.println("(4) Faculty's no-arg constructor is invoked");  
    }  
}  
  
class Employee extends Person {  
    public Employee() {  
        this("(2) Invoke Employee's overloaded constructor");  
        System.out.println("(3) Employee's no-arg constructor is invoked");  
    }  
  
    public Employee(String s) {  
        System.out.println(s);  
    }  
}  
  
class Person {  
    public Person() {  
        System.out.println("(1) Person's no-arg constructor is invoked");  
    }  
}
```

5. Invoke Person() constructor

# Trace code

```
public class Faculty extends Employee {
    public static void main(String[] args) {
        new Faculty();
    }

    public Faculty() {
        System.out.println("(4) Faculty's no-arg constructor is invoked");
    }
}

class Employee extends Person {
    public Employee() {
        this("(2) Invoke Employee's overloaded constructor");
        System.out.println("(3) Employee's no-arg constructor is invoked");
    }

    public Employee(String s) {
        System.out.println(s);
    }
}

class Person {
    public Person() {
        System.out.println("(1) Person's no-arg constructor is invoked");
    }
}
```

6. Execute println

# Trace code

```
public class Faculty extends Employee {
    public static void main(String[] args) {
        new Faculty();
    }

    public Faculty() {
        System.out.println("(4) Faculty's no-arg constructor is invoked");
    }
}

class Employee extends Person {
    public Employee() {
        this("(2) Invoke Employee's overloaded constructor");
        System.out.println("(3) Employee's no-arg constructor is invoked");
    }

    public Employee(String s) {
        System.out.println(s);
    }
}

class Person {
    public Person() {
        System.out.println("(1) Person's no-arg constructor is invoked");
    }
}
```

7. Execute println

# Trace code

```
public class Faculty extends Employee {
    public static void main(String[] args) {
        new Faculty();
    }

    public Faculty() {
        System.out.println("(4) Faculty's no-arg constructor is invoked");
    }
}

class Employee extends Person {
    public Employee() {
        this("(2) Invoke Employee's overloaded constructor");
        System.out.println("(3) Employee's no-arg constructor is invoked");
    }

    public Employee(String s) {
        System.out.println(s);
    }
}

class Person {
    public Person() {
        System.out.println("(1) Person's no-arg constructor is invoked");
    }
}
```

8. Execute println

# Trace code

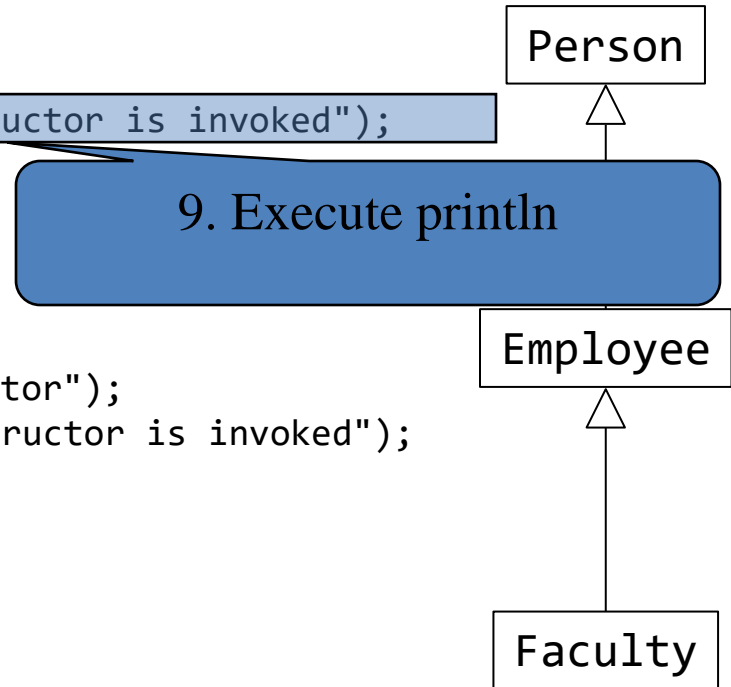

```
public class Faculty extends Employee {  
    public static void main(String[] args) {  
        new Faculty();  
    }  
}
```

```
public Faculty() {  
    System.out.println("(4) Faculty's no-arg constructor is invoked");  
}
```

```
class Employee extends Person {  
    public Employee() {  
        this("(2) Invoke Employee's overloaded constructor");  
        System.out.println("(3) Employee's no-arg constructor is invoked");  
    }  
}
```

```
public Employee(String s) {  
    System.out.println(s);  
}
```

```
class Person {  
    public Person() {  
        System.out.println("(1) Person's no-arg constructor is invoked");  
    }  
}
```

# Default constructor

- Remember, a class may be defined without constructors
- In this case, a no-arg constructor with an empty body is *implicitly* defined in the class
- This constructor, called a *default constructor*, is provided automatically *only if no constructors are explicitly defined in the class*
- **Best practice is to provide (if possible) a no-arg constructor for every class to make the class easy to extend and avoid compile-time errors during constructor chaining**

# Defining a subclass

- A subclass inherits from a superclass
- You can also
  - Add new properties
  - Add new methods
  - Override the methods of the superclass

# Add new methods

- For example
  - Add `printCircle()` method in the `Circle` class

```
public void printCircle() {  
    System.out.println("The circle is created " +  
        getDateCreated() + " and the radius is " + radius);  
}
```

Call superclass method

# Override the methods of the superclass

- A subclass inherits methods from a superclass
- Sometimes it is necessary for the subclass to modify the implementation of a method defined in the superclass
- This is referred to as *method overriding*

# Override the methods of the superclass

- To override a method, the method must be defined in the subclass using **the same signature** as in its superclass, and **same or subtype of the overridden method's return type**
- A best practice to avoid mistakes is to use a special Java syntax, called *override annotation*
  - Annotated method is required to override a method in its superclass
    - If it does not, then there will be a compile-time error

```
public class Circle extends GeometricObject {  
    // Other methods are omitted
```

```
    @Override
```

```
    public String toString() {  
        return super.toString() + "\nradius is " + radius;  
    }
```

```
}
```

# Overriding vs overloading

- Overridden methods
  - Have the same signature
  - Are in different classes related by inheritance
- Overloaded methods
  - Have the same name, but different parameter lists
  - Can be either
    - In the same class
    - In different classes related by inheritance

# Overriding vs overloading

```
public class Test {
    public static void main(String[] args) {
        A a = new A();
        a.p(10);
        a.p(10.0);
    }
}

class B {
    public void p(double i) {
        System.out.println(i * 2);
    }
}

class A extends B {
    // This method overrides the method in B
    public void p(double i) {
        System.out.println(i);
    }
}
```

```
public class Test {
    public static void main(String[] args) {
        A a = new A();
        a.p(10);
        a.p(10.0);
    }
}

class B {
    public void p(double i) {
        System.out.println(i * 2);
    }
}

class A extends B {
    // This method overloads the method in B
    public void p(int i) {
        System.out.println(i);
    }
}
```

Remember to use `@Override` annotation  
(not shown so lines align)

# Private methods of the superclass

- An instance method can be overridden only if it is accessible
- As such, a **private method cannot be overridden** because it is not accessible outside its own class
- **If a method defined in a subclass is private in its superclass, then the two methods are completely unrelated**

# Static methods of the superclass

- Like an instance method, a static method can be inherited
- However, a **static method cannot be overridden**
- **If a static method defined in the superclass is redefined in a subclass, the method defined in the superclass is hidden**

# this and super keywords

- Similar to using `this` to reference the calling object, the keyword `super` refers to the superclass of the class which `super` appears
- The keyword `this` is the name of a reference that refers to an object itself
  - One common use of the `this` keyword is to reference a hidden *class* member
- The keyword `super` refers to the superclass of the class in which `super` appears
  - One common use of the `super` keyword is to reference a hidden *superclass* member

# this keyword

- The keyword `this` refers to an object itself
- The keyword `this` can be used to
  - Call another constructor of the same class
    - Syntax  
`this(arguments);`
  - Reference a hidden class variable
    - Syntax  
`this.variableName`

# super keyword

- The keyword `super` refers to the superclass of the class in which `super` appears
- The keyword `super` can be used to
  - Call a superclass constructor
    - Syntax  
`super(arguments);`
  - Call a superclass method
    - Syntax  
`super.methodName(arguments);`

# The Object class and its methods

- Every class in Java is descended from the `java.lang.Object` class
- If no inheritance is specified when a class is defined, the superclass of the class is `Object`

```
public class Circle {  
    ...  
}
```

Equivalent

```
public class Circle extends Object {  
    ...  
}
```

# The toString() method in Object

- The toString() method returns a string representation of the object
- The default implementation returns a string consisting of a class name of which the object is an instance, the at sign (@), and a number representing this object
- For example

```
Loan loan = new Loan();
System.out.println(loan.toString());
```

  - The code displays something like Loan@15037e5
  - This message is not very helpful or informative
  - Usually, you should override the toString method so that it returns a digestible string representation of the object

# Next Lecture
